

TASK 2 – API Integration & JSON Handling

Project Title:

Weather Information Finder using Python API

1. Objective

The objective of this project is to learn API integration and JSON handling using Python. The project fetches real-time weather data from an external API and displays important weather information based on user input.

2. Technologies Used

- Python
- Requests Library
- OpenWeatherMap API

3. Features

- Fetches weather data using API
- Parses JSON responses
- Searches weather by city name
- Displays temperature, humidity, and weather condition
- Uses try-except error handling
- Handles invalid city names and API errors

4. Code Explanation

The program takes a city name as input from the user and sends an HTTP request to the OpenWeatherMap API using the Requests library. The API returns weather information in JSON format. The program extracts important weather details such as temperature, humidity, weather description, and wind speed from the JSON response and displays them to the user. Proper exception handling is implemented using try-except blocks.

5. Source Code

```
import requests

# Your API key from OpenWeatherMap
API_KEY = "96fe4e5b45bf87c217596e65e1f5075d"

# Base URL of the API
BASE_URL = "https://api.openweathermap.org/data/2.5/weather"

def get_weather(city):
    """
    Fetch weather data from API
    """
    # Parameters sent to API
    params = {
        "q": city,
        "appid": API_KEY,
        "units": "metric"
    }
    try:
        # Sending GET request to API
        response = requests.get(BASE_URL, params=params)

        # Convert JSON response into dictionary
        data = response.json()

        # Handle API errors
        if response.status_code != 200:
            print("API Error:", data.get("message"))
            return None

        return data

    except requests.exceptions.ConnectionError:
        print("Connection Error! Check internet.")
    except requests.exceptions.Timeout:
        print("Request Timed Out!")
    except requests.exceptions.RequestException as e:
        print("Something went wrong:", e)

    return None

def display_weather(data):
    """
    Display important weather information
    """

    # Extracting data from JSON response
    city = data["name"]
    country = data["sys"]["country"]
    temperature = data["main"]["temp"]
    humidity = data["main"]["humidity"]
    weather = data["weather"][0]["description"]
    wind_speed = data["wind"]["speed"]

    print("\n===== WEATHER REPORT =====")
    print(f"City: {city}, {country}")
    print(f"Temperature: {temperature}°C")
    print(f"Humidity: {humidity}%")
```

```
print(f"Weather: {weather}")
print(f"Wind Speed: {wind_speed} m/s")
print("=====")

def main():
    print("\n☀️ WEATHER INFORMATION FINDER ☀️")

    # User input
    city = input("Enter city name: ")

    # Fetch weather data
    weather_data = get_weather(city)

    # Check if data exists
    if weather_data:
        display_weather(weather_data)
    else:
        print("Could not fetch weather data.")

if __name__ == "__main__":
    main()
```

6. Output Screenshots

API REQUEST CODE

```
# Parameters sent to API
params = {
    "q": city,
    "appid": API_KEY,
    "units": "metric"
}

try:
    # Sending GET request to API
    response = requests.get(BASE_URL, params=params)

    # Convert JSON response into dictionary
    data = response.json()
```

SUCCESSFUL OUTPUT

The screenshot shows a VS Code editor with a file explorer on the left, a code editor in the center, and a terminal at the bottom. The code editor displays a Python script named `main.py` with the following content:

```
10 def get_weather(city):
43     print("Something went wrong:", e)
44
45     return None
46
47
48 def display_weather(data):
49     """
50     Display important weather information
51     """
52
53     # Extracting data from JSON response
54     city = data["name"]
55     country = data["sys"]["country"]
56     temperature = data["main"]["temp"]
57     humidity = data["main"]["humidity"]
58     weather = data["weather"][0]["description"]
59     wind_speed = data["wind"]["speed"]
60
61     print("\n===== WEATHER REPORT =====")
62     print(f"City: {city}, {country}")
63     print(f"Temperature: {temperature}°C")
```

The terminal at the bottom shows the command `python main.py` being executed. The output is as follows:

```
PS C:\KARTHIK-DRIVE\Alfido_Python_dev_tasks\TASK-2 API Integration and JSON Handling> python main.py
WEATHER INFORMATION FINDER
Enter city name: Bangalore

===== WEATHER REPORT =====
City: Bengaluru, IN
Temperature: 29.34°C
Humidity: 5%
Weather: overcast clouds
Wind Speed: 4.93 m/s
```

ERROR HANDLING OUTPUT

The screenshot shows a terminal window with the following output:

```
PS C:\KARTHIK-DRIVE\Alfido_Python_dev_tasks\TASK-2 API Integration and JSON Handling> python main.py
WEATHER INFORMATION FINDER
Enter city name: adhoieic
API Error: city not found
Could not fetch weather data.
PS C:\KARTHIK-DRIVE\Alfido_Python_dev_tasks\TASK-2 API Integration and JSON Handling>
```

7. Conclusion

This project helped in understanding API Integration, JSON handling, HTTP requests, real-time data fetching, and exception handling using Python.
